

## Asymptomatic giant mucocele

ISMAEL AOMAR MILLÁN, LAURA PÉREZ FERNÁNDEZ, SUSANA MOYA ROLDÁN

Department of Internal Medicine. Hospital Clínico San Cecilio de Granada, Spain.

Intracranial mucoceles are benign cysts caused by mucous retention inside a sinus secondary to obstruction of its drainage orifice. These cysts are rare and most often appear in frontal sinuses (60%).

The most frequent symptomatology is intraorbital or paranasal with complications such as meningitis, meningoencephalitis or pneumocephalus among others developing if the frontal mucocele erodes the posterior wall.

Polyposis or malignant nasosinusal tumours

should be included within the differential diagnosis.

Treatment varies from conservative measures to surgery. We present the case of an 85-year-old male who was diagnosed with a giant mucocele of the frontal sinus using cranial computerised tomography (CT) on suspicion of stroke. The CT demonstrated a left frontal lesion which was eroding the bone (Figure 1) and which was found to be a mucocele of biopsy by nasal endoscopy. Conservative treatment was administered.

**Figure 1.** Cranial computerised tomography image in which a lesion of the left frontal sinus with associated bone erosion may be observed.
